

Iowa's Impaired Waters

You've likely heard of Iowa's many "impaired" waters. As the DNR prepares the latest version of the state's "impaired waters list," it's important to understand what makes a water impaired, and more importantly, what we can all do to take streams and lakes off the list.

2006 Impaired Waters List

Lakes and stretches of streams and rivers in Iowa each have specific designations, based on what they are used for—like recreation, such as swimming or fishing; drinking water; or maintaining a healthy population of fish and other aquatic life.

Every two years, Iowa must report on its progress in meeting water quality goals to the U.S. Environmental Protection Agency. The state prepares a report, called the 305(b) report that shows how well Iowa waters are meeting those goals. The report includes waters that meet the designated uses, waters that we need more information about and waters that are impaired (see page 3).

If the water quality in the stream or lake prevents it from meeting its designated use, it does not meet Iowa's water quality standards and is considered "impaired."

The waterbody is then placed on the "303(d)" list, commonly referred to as the "impaired waters list." This is named after section 303(d) of the federal Clean Water Act and means that the stream or lake needs a water quality improvement plan written (also known by a technical name, "Total Maximum Daily Load," or "TMDL").

The water quality improvement plan outlines water quality problems, identifies sources of the problem,

identifies needed reductions in pollutants and offers possible solutions. Water quality improvement plans are approved by the U.S. Environmental Protection Agency and then the waters are moved off the 303(d) list. Even though a water moves off the 303(d) list, the waterbody is still considered impaired until water quality improves.

While the water quality improvement plan can offer ideas for solutions, and the DNR can provide technical or financial assistance for Iowans looking to organize a watershed improvement project, local groups need to take action and work with the DNR to actually improve their stream or lake.

Local action can lead to improved water quality, which can help the stream or lake meet state water quality standards again. When the waterbody meets those standards, it may be able to come off the impaired waters list.

Inside:

- What the list means for Iowa lakes and streams
- Answers to commonly asked questions
- What you can do to help Iowa's impaired waters

What’s a waterbody?

For the impaired waters list, waterbodies are defined as Iowa lakes, streams and wetlands that have assigned water use designations. When it comes to streams and rivers, they are split into segments based on different designated uses.

For example, a segment of the Cedar River near Cedar Rapids is designated for drinking water, while a portion of the same river near Waverly is protected for other uses. If one segment is impaired, that does not mean the entire stream or river is impaired. However, improving the entire watershed, or area of land that drains to the stream, can have an impact on water quality in the impaired segment.

Not all waterbodies in Iowa are assessed for the 2006 list, because water quality monitoring has not been conducted on many of our lakes and streams.

Top 10 Causes of Impairment in Rivers/Streams		
Rank	Cause Name	Number of Stream/ River Segments *
1	Cause Unknown (biological)	120
2	Habitat alterations	104
3	Low dissolved oxygen	77
4	Siltation	66
5	Indicator bacteria	65
6	Ammonia	61
7	Nutrients (nitrogen/phosphorus)	33
8	Flow alteration	21
9	Unknown toxicity	13
10	Other (fish kills; unknown cause)	10

Top 10 Causes of Impairment in Lakes		
Rank	Cause Name	Number of Lakes *
1	Turbidity	50
2	Algal Growth	43
3	Nutrients	32
4	Noxious aquatic plants	28
5	pH	24
6	Siltation	24
7	Indicator bacteria	18
8	Suspended solids	15
9	Other (fish kills; unknown cause)	12
10	Low dissolved oxygen	10

*These charts show the top 10 reasons waters are impaired in Iowa. Lakes and streams may be impaired for more than one cause. Biological impairments are the number one impairment in streams, but are difficult to trace to a specific cause.

Consequently, we don’t have the information to determine whether they are impaired or not.

What does “impaired” really mean? Is the water unsafe?

A waterbody is impaired when its water quality does not support that waterbody’s designated uses for human contact, aquatic life or drinking water. Some of these impairments, like high nitrate levels in the Raccoon and Cedar rivers, could pose a risk to Iowan’s drinking water if not treated for nitrate removal or mixed with other sources of drinking water to lower nitrate levels. The decline in freshwater mussels in many Iowa streams also indicates a severe water quality problem. However, most impaired waterbodies in Iowa are generally not grossly polluted.

“The majority of impairments in Iowa waters are minor. Iowa’s water quality standards are designed to alert us to a potential problem before serious pollution problems begin,” said John Olson, the DNR’s specialist on water quality assessments. “For the most part, when a water is impaired, it tells us that we, as Iowans, need to act before those problems becomes severe.”

Why don’t these waters meet their designated use?

High bacteria levels can present health risks for those swimming, wading and playing in the water. Excess nutrients such as nitrogen and phosphorus, and sediment make it difficult for fish, plants and other aquatic life to thrive. As for drinking water, high levels of nitrate and other chemicals often call for additional treatment and higher costs. For example, the Des Moines Water Works built the world’s largest nitrate removal facility because of extremely high nitrate levels in the Raccoon River, one of its sources for drinking water.

If a water doesn’t meet its designated use for recreation, is it unsafe?

In most cases, an impairment indicates that there is a minor problem and that we need to address it before it becomes severe. However, there are waters in Iowa with serious pollution problems.

Beaches are generally protected for swimming, although monitoring at Iowa’s 37 state park beaches, shows that indicator bacteria exceeded the levels for impairment nearly 8 percent of the time since monitoring began in 2000.

However, even when bacteria levels are high the fish are safe to eat when properly cooked, unless the waterbody has a listed fish consumption advisory. Only a few lakes have had fish consumption advisories.

What do the impairments mean?

Waterbodies can be impaired because water monitoring shows high levels of pollutants, like nutrients, sediment or chemicals. Streams and lakes can also be impaired when biological monitoring finds that fish and other aquatic life populations aren't as diverse or numerous as they should be.

By looking at the types and numbers of species, including fish, plants, insects and other aquatic creatures, scientists can make conclusions about water quality. The presence of certain species, especially in high numbers, indicate good water quality, while other species can tolerate higher levels of pollution. Investigators also look to see if species are stressed or diseased.

Biological impairments are difficult to trace to a specific cause. Likely causes include siltation which can reduce spawning success or insect hatches, low dissolved oxygen, and excess nutrients such as nitrogen or phosphorus which can cause algal blooms.

As water quality improves, the fish and other aquatic life populations should grow and diversify, resulting in better biological communities.

What does the list say about water quality in Iowa?

The most common impairments in Iowa streams are due to unknown causes affecting the biological communities, altered habitats, low oxygen levels and siltation. In lakes most impairments are due to turbidity (cloudy water), algal growth and excess nutrients.

While the 2006 list includes more impaired waters than previous lists, it does not mean that water quality is worse in Iowa. It indicates that more monitoring has been done and more data has been collected than in previous years.

It may also seem easy to compare the number of impaired waters to surrounding states. Because there are so many varying factors in determining a state's list, this is an inaccurate comparison, like comparing apples and oranges.

**“OUR WATERS DIDN'T
BECOME POLLUTED
OVERNIGHT, AND CLEANUP
CAN NOT ALWAYS HAPPEN
QUICKLY, EITHER.”
- DIRECTOR RICH LEOPOLD**

Water quality in Iowa has also drastically improved since the advent of the Clean Water Act in the 1970s, which put controls on industrial and city sewage discharges into streams and rivers.

“It's been long enough since the Clean Water Act that many of us don't recall how poor water quality conditions were then, with raw, untreated sewage and other discharges going directly into our waters,” Olson said. “Our waters are much better now, but we still have work to do, including addressing pollution from nonpoint sources.”

Nonpoint source pollution, especially sediment, nutrients and bacteria, washes into Iowa's streams and lakes from farm fields, forested lands and urban areas. Those pollutants come from an area called a “watershed,” which is an area of land that drains into a lake or stream.

“With the majority of our pollution problems coming from nonpoint sources, it can be more difficult to clean up than stopping a discharge from a pipe,” said DNR Director

Impaired Waters - Integrated Report

EPA requires that states assess their water quality every two years. EPA's recommended reporting format is called the “Integrated Report.” States are asked to place their waters into one of five categories. Waters that were assessed and found not to be impaired are included in categories 1 and 2. Impaired waters are listed in categories 4 and 5, while category 3 consists of waters that were assessed but did not have enough data to qualify as impaired or unimpaired.

Category	Description of the Category	Number of Waters
Category 1	All designated uses are met	187
Category 2	Some of the designated uses are met, but there are insufficient data to determine if the remaining uses are met.	258
Category 3	Insufficient data to determine whether any designated uses are met.	1,224
Category 4	Waterbody is impaired, but already has or does not need a water quality improvement plan written	92
Category 5	Waterbody is impaired and needs a water quality improvement plan.	274

Rich Leopold. “But it’s not impossible. Iowans are working hard to improve water quality, and we’re seeing results. That gives us more reason to continue to step up our water quality improvement efforts.”

Did any streams or lakes come off the list?

While 41 waterbodies moved off the 303(d) list because water quality improvement plans were written (see table on page 3 for explanation), no waters came off the impaired waters list because water quality improved enough to meet water quality standards.

“Water quality improvements are long-term projects. Our waters didn’t become polluted overnight, and cleanup can not always happen quickly, either,” said Leopold. “We have many water quality projects underway, more planned, and we’re seeing improvements. However, it may be a few years before those improvements are great enough to help waterbodies come off the impaired waters list.”

Projects across the state, like those at Nine Eagles, Slip Bluff lakes and in northeast Iowa’s trout streams have all seen improvements in water quality. For example, the average water clarity at Slip Bluff increased from 4.3 to 11.8 feet between 2000 and 2006. In 1980, only six trout streams were clean and healthy enough to allow trout to reproduce naturally - the other streams depended on stocking to keep populations alive. Today, thanks to water quality improvement projects, 32 trout streams sustain naturally reproducing trout.

Beneficial Use Impaired	Totals
Primary contact recreation	124
Aquatic life	188
Drinking water	16
Fish consumption	9
General use only	19

Includes only category 5 waters (impaired waters without a water quality improvement plan written). Totals are not cumulative because a water body can have more than one impairment.

The DNR and many Iowans also put great effort into maintaining our high quality waters to ensure they don’t reach the impaired waters list.

Why were streams and lakes added to the list?

The DNR added about 135 new waterbodies to the 2006 list, generally because water monitoring and biological monitoring data were not available for these streams and lakes prior to the 2006 list.

“IOWANS ARE WORKING HARD TO IMPROVE WATER QUALITY, AND WE’RE SEEING RESULTS.” - DIRECTOR RICH LEOPOLD

In all, there are 366 impaired waters. This includes 92 waters that have a water quality improvement plan written but remain impaired.

When were data collected for the list?

The EPA requires the DNR to submit an impaired waters list every two years.

The 2006 impaired waters list reflects water quality data collected from 2002 to 2004. The 2008 impaired waters list will reflect data gathered in 2005 and 2006.

How can I comment on the list?

You can find the draft version of the impaired waters list, as well as instructions on submitting a comment, on the DNR website at www.iowadnr.gov/water/watershed/impaired.html.

What will happen to my comments?

Your comments will be carefully considered as the DNR finalizes the list before sending it to the U.S. Environmental Protection Agency for approval.

What’s next?

After the public comment period ends, the DNR will revise the draft list and submit it to the EPA. The EPA will then approve the list or make revisions. Then the final list is returned to the DNR.

Once the impaired waters list is finalized, the DNR will use the list to help prioritize water quality efforts. It’s also important for Iowans to take ownership of the waters on the list and work locally with the DNR and other organizations to improve our waters.
